

Measurement Units

When we start a new project in Blender, the Metric system is used by default, with one Blender unit of distance set equivalent to one metre. This means that our default Cube is 2 metres in all three directions.

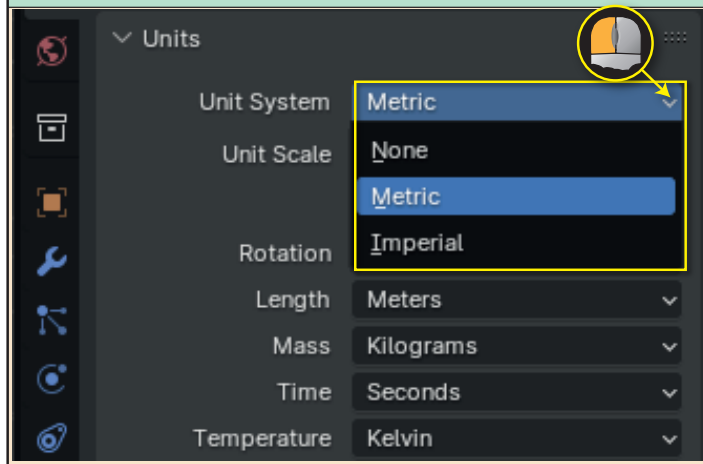

We can see the size of an object in both the **Last Op** panel when the object is created, and also in the **Sidebar's Item** page where the size in each of the three dimensions is given.

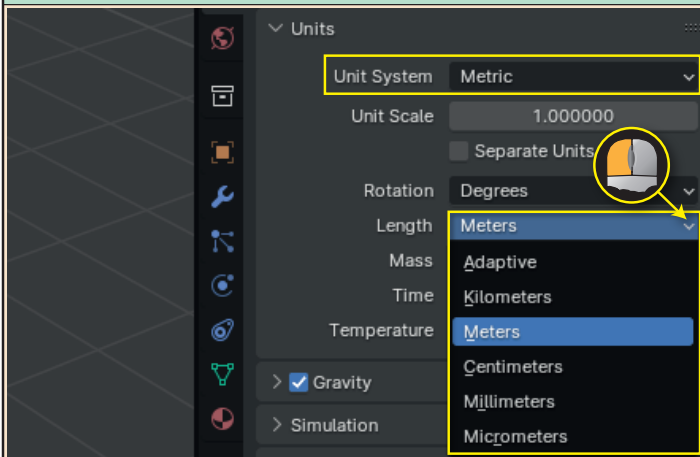

The units we are using can be set in the **Scene** page of the **Properties Editor**.

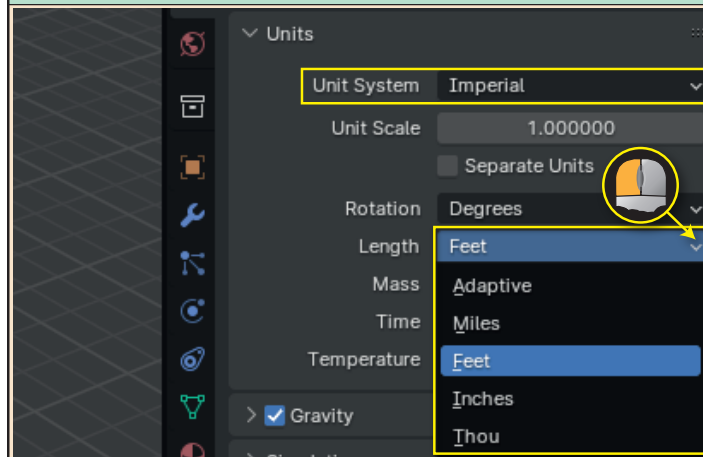

Unit System gives us a choice of **Metric** or **Imperial** with a third option, **None**, removing any link between real-world size and Blender measurement units.

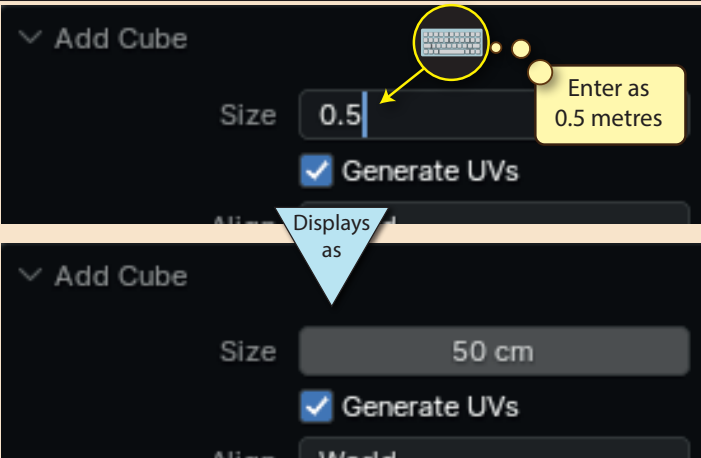

When we choose **Metric**, the **Length** field lower down the list of fields offers measurement units of anything from a kilometre down to a micrometre.

When we choose **Imperial**, we get the old British measurements which are still used in the USA. This ranges from miles to thou (one thousandth of an inch).

Both *Metric* and *Imperial* have a *Length* option labelled **Adaptive**. This allows Blender to use the most appropriate units when displaying values. For example, if we are working in *Metric* and create a Cube defining its size as 0.5 metres, Blender displays 50cm.

Separate Units is a checkbox, which, when selected, shows named units rather than fractions where possible. Here, when working in *Imperial*, we have created a Cube which has a size of 2.5 feet this is then displayed as 2 feet 6 inches.

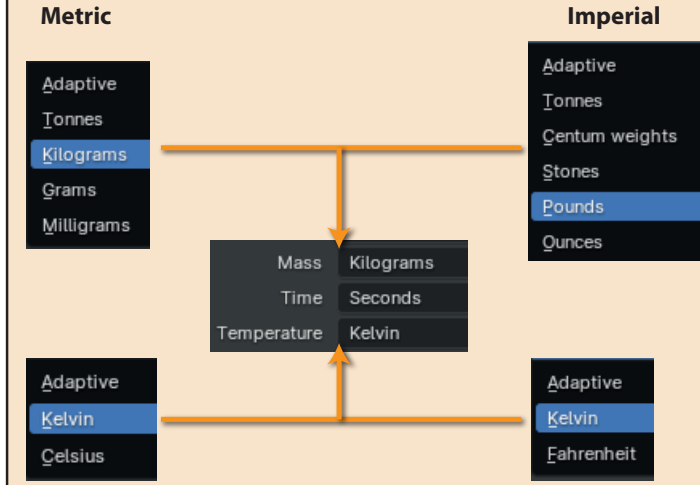

If you are not familiar with the Imperial system, the tick marks by the numbers - properly called "prime" and "double prime" - are the shorthand used for "feet" and "inches".

Rotation can be set to *degrees* or *radians*.

Mass, Time, and Temperature are only of use when we are using physics to create realistic animations. But note that *Mass* and *Temperature* have different settings for *Metric* and *Imperial*.

Unit Scale should scale distances appropriately. But, making use of it causes display problems as shown below when a 2 metre Cube is created. So, it is best to ignore this field, leaving it set to 1.0.

However, **Scale** in the **Viewport Overlays** panel can be adjusted when working on a different scale from the default metres or feet. For example, setting **Scale** to **0.001** when using metric, will set the smallest grids shown in named and user views to exactly 1mm.
